

Smart Watch Troubleshooting Guide (Q&A Format)

Q1: Why can't the watch power on / the watch looks intact but totally unresponsive?

A: This issue is mostly caused by improper charging operation instead of hardware defects.

1. Please charge the watch for a full 2 hours with a standard 5V charger. Fast chargers are forbidden, as they will damage the built-in battery and lead to boot failure.
2. Functions like Always-On Screen, high brightness and continuous notification alerts consume power rapidly, which may drain the battery completely and cause shutdown.
3. Outdated firmware will trigger system crash. After full charging, connect the watch to DaFit App and upgrade to the latest firmware to restore normal startup.

Q2: The watch broke down within one month. How to solve this?

A: Repeated abnormal functions may be caused by incorrect daily operation without standard guidance.

1. Complete all calibration steps in DaFit App after receiving the watch: fill in accurate personal data, adjust wearing position and update firmware first.
2. Follow official charging and power-saving rules daily to avoid battery damage and sensor failure.

3. If issues still persist after all troubleshooting steps, contact our customer service for free return, exchange or full refund support.

Q3: Why the watch cannot record steps, calories and other health metrics at all?

A: The tracking algorithm relies on standardized setup and wearing methods, please check the below points:

1. Enter correct personal information (gender, age, height, weight) in DaFit App; wrong data will distort motion calculation and result in zero tracking data.
2. Wear the watch tightly 2 fingers above the wrist bone. Loose wearing or covering the sensor with sleeves will block data collection.
3. The watch only records valid data after continuous walking over 40 steps; slight arm swings, handshakes and small gestures cannot trigger counting.

Q4: Why health & step tracking still does not work when man restarted the watch and reconnected the DaFit App?

A: Simple restart cannot fix tracking failures caused by outdated firmware or sensor misconfiguration, follow these steps:

1. Open DaFit App, enter the device page and upgrade the watch firmware to the newest official version to fix sensor logic bugs.
2. Remove and re-pair the watch with your phone, then re-input all

personal physical parameters again.

3. Wear the watch tightly and keep your arm steady during health measurement; avoid violent arm shaking when walking.

4. If the problem still exists after all operations, reach out to customer service for one-on-one technical support.
